1 Introduction and scope

This report describes the calculation procedure and data considered in order to design the structure of a new apartment building in Eau Claire, Wisconsin.

The construction consists in a three-story apartment building with a first-floor footprint of about 19,500 square feet, a below-grade parking garage with a footprint of about 27,200 square feet, perimeter retaining walls, a slab-on-grade, and a conventional foundation system.

The first floor system is precast hollow core concrete plank on precast beams and columns. For the upper floors and roof, the system is wood-framed. Retaining walls and slab on grade are comprised of cast in place concrete, except for three reinforced CMU walls next to the garage aisles, that will be demolished during the second phase of construction.

The foundation uses conventional cast in place concrete footings to transfer axial compression and lateral loads to the ground.

2 Building codes

The following building and material codes were used for the design:

- Building code
 - International Building Code, 2018 Edition (IBC 2018) with reference to Minimum Design Loads for Buildings and Other Structures by the American Society of Civil Engineers, 2016 Edition (ASCE 7).
- Material codes
 - Reinforced Concrete: Building Code Requirements for Structural Concrete and Commentary by the American Concrete Institute, 2019 Edition (ACI 318).
 - Masonry: Building Code Requirements and Specification for Masonry Structures and Companion Commentaries, 2013 Edition (ACI 530/530).

3 Loading criteria

A summary of the project-specific loading criteria follows (see appendix A for a detailed list of load values).

3.1 Gravity loading

The gravity loads listed in Table 1 are in addition to the self weight of the structure. The minimum loading requirements were taken from ASCE 7 as well as the loading criteria supplied by the engineer of record. Loads are given in pounds per square foot (psf).

In addition to these uniform slab loads, a perimeter dead load of 12 psf was applied to the structure to account for the weight of the cladding system.

3.2 Wind design criteria

Wind loading is in accordance with the IBC and ASCE 7 requirements as shown in Table 2.

3.3 Snow loading

Wind loading is in accordance with the ASCE 7 requirements as shown in Table 3.

8.2 Trusses

8.2.1 Introduction

The calculations shown below correspond to the dimensioning of the floor structure carried out during the design of the building. These calculations have been superseded by those provided by the truss manufacturer.

(a) The design values in this table correspond with those published in the 2005 edition of the AF&PA American Wood Council's *Allowable Stress Design (ASD)/LRFD Manual for Engineered Wood Construction* Tables M9.2.1 - M9.2.4, which are available from the AF&PA American Wood Council.

(a1) In late January 2008, revised Axial EA 90° (perpendicular) values were submitted for modification to AF&PA based on an industry-wide consensus. The appropriate panel grade and construction adjustment factor, C_s , has already been incorporated into these design values—do not apply the C_s factor a second time. These values do not apply to Structural I panels. See Tables M9.2.1 - M9.2.4 for the appropriate multipliers for Structural I panels.

(b) Shear through the thickness design capacities are limited to sections two feet or less in width; wider sections may require further reductions.

(c) Strength axis is defined as the axis parallel to the face and back orientation of the flakes, which is generally the long panel direction, unless otherwise marked.

Figure 11: Wood structural panel design capacities based on span ratings.

$$q_{live} = 1.92 \text{ kN/m}^2 (40 \text{ psf}) \quad (34)$$

$$q_{dead} = 0.72 \text{ kN/m}^2 (15 \text{ psf}) \quad (35)$$

The allowable live load deflection is span/540 and the allowable total load deflection span/360.

Structural design of the panels.

Mechanical properties of the plywood panel. The mechanical properties used to compute the floor deflection are its stiffness $EI = 1977 \text{ MPa}$ and its thickness $t = 15.09 \text{ mm}$ (19/32 inch). Each layer works independently, otherwise said, they are connected only over the joists.

Bending stiffness. The deflection obtained under live load is:

$$\Delta_{LL} = 1.24 \text{ mm} = \frac{\text{span}}{629} < \frac{\text{span}}{540} \implies OK \quad (36)$$

and the deflection under total load is:

$$\Delta_{TL} = 1.68 \text{ mm} = \frac{\text{span}}{484} < \frac{\text{span}}{360} \implies OK \quad (37)$$

Bending strength. The allowable bending stress for the OSB panel is $F_b = 5.62 \text{ MPa}$ (the panel grade and construction factors are already been applied to this capacity). The load duration factor for the live load on the corridor is $C_D = 1.6$. The adjusted allowable bending stress is therefore $F'_b = 8.98 \text{ MPa}$.

The maximum bending stress obtained under total load (three-span condition) is:

$$\sigma_{max} = 2.41 \text{ MPa} < 6.94 \text{ MPa} = F'_b \implies OK \quad (38)$$

(a) The values in this table correspond with those published in the 2005 edition of the AF&PA American Wood Council's *Commentary National Design Specification (NDS) for Wood Construction ASD/LRFD* Table C9.2.3, which is available from the AF&PA American Wood Council.

(b) The predominant thickness for each span rating is highlighted in **bold**.

Figure 12: Relationship between span rating and nominal thickness for OSB.

Shear strength. The allowable shear stress of the panel is $F_v = 0.19 \text{ MPa}$ and the adjusted allowable shear stress is (under the same conditions that we used for the bending stress) $F'_v = 0.30 \text{ MPa}$.

The maximum shear stress obtained under total load is:

$$\tau_{max} = 0.05 \text{ MPa} < 0.30 \text{ MPa} = F'_v \implies OK \quad (39)$$

Fire design of the panels. According to the table 9 the time assigned to a 19/32 inch panel is 15 minutes, so after 30 minutes of fire only one of the three panels remains in place. Accordingly, we perform the bending and shear checks to the remaining panel.

Bending strength. The maximum bending stress obtained under total load (three-span condition) is:

$$\sigma_{max} = 4.59 \text{ MPa} < 8.98 \text{ MPa} = F'_b \implies OK \quad (40)$$

Shear strength. The maximum shear stress obtained under total load is:

$$\tau_{max} = 0.08 \text{ MPa} < 0.30 \text{ MPa} = F'_v \implies OK \quad (41)$$

8.3.2 Corridor Joists

Simply supported 4x6 southern pine joists span a maximum of $L = 2.49 \text{ m}$ (94.25 inches) and are spaced at $s = 0.81 \text{ m}$ (32 inches). The design loads are:

$$q_{live} = 1.92 \text{ kN/m}^2 (40 \text{ psf}) \quad (42)$$

$$q_{dead} = 0.72 \text{ kN/m}^2 (15 \text{ psf}) \quad (43)$$

Timber decking nailed to the compression edge of the joists provides lateral bracing for at least the same fire resistance time as the joists (i.e. $C_L = 1.0$).

9.1 Structural model

A three-dimensional elastic computer model of the substructure is analyzed using XC. The model includes first floor frame and columns (see figure 26). The hollow core planks are modelled using shell elements, while beams and columns are modelled using frame elements. Loads transmitted by 2nd, 3rd floors and roof are applied to the 1st. Load layout is shown in figure 35. See in figures 27 to 34 load distribution for each load case.

Linear loads are expressed in kN/m and surface loads in kN/m², where:

$$\begin{aligned}1 \text{ kN/m} &= 68.52178 \text{ lb/ft} \\1 \text{ kN/m}^2 &= 20.885434 \text{ psf}\end{aligned}$$

9.3 Basement walls

9.3.1 Introduction

The design is based in the following assumptions:

- Design wall with pinned base and pinned top.
- Neglect corner regions (wall spans one-way only).
- Top slab is in place and has achieved full strength prior to back-filling.
- Vehicular traffic around the building is represented by a uniform load of 250 psf (11.97 kN/m^2).

11 Balconies connection

11.1 Loads on the connection

The ties of the balconies are attached to the wood structure by means of the connection represented in figure 133.

According to our calculations the maximum load to be resisted by this connection is:

$$F = 4.83 \text{ kN} \quad (194)$$

the angle with respect to the vertical of this force is 23.42 degrees.

11.2 Loads on fasteners

To calculate the loads on the connection fasteners we have used a the finite element model shown in figure 135.

11.3 Fastener strength

The strength of the 3/8 lag screws are as follows:

- Screw design withdrawal: $W_d = 4.6 \text{ kN}$.
- Screw design lateral strength: $Z_d = 0.89 \text{ kN}$.

11.4 Checking of fastener capacities

The capacities of the fasteners are as follows:

Screw ID	Z (kN)	R (kN)	CF -
466	0.13	0.98	0.14
638	0.96	1.03	0.93
129	0.15	1.19	0.12

50	0.64	2.66	0.24
26	0.13	1.40	0.10

490	0.64	2.66	0.24
322	0.13	1.40	0.10
297	0.70	1.21	0.58

where

Screw ID. Screw identifier.

Z: Screw strength.

R: Design load on screw.

$CF = Z/R$: Capacity factor

We can see that the maximum capacity factor is $0.93 < 1$ so the fasteners are strong enough.
